FINITE MASS CORRECTIONS IN ORBIFOLD GAUGE THEORIES [a]

The Standard Model Higgs boson can be identified with the extra dimensional component of a gauge boson in a higher dimensional theory where the gauge group is broken to the Standard Model group by the orbifold action. In that case the Standard Model symmetry can be radiatively broken by the Hosotani mechanism and the Higgs boson mass is protected from bulk quadratic divergences by the higher dimensional gauge theory without any need of supersymmetry. However the latter does not protect a priori the Higgs mass from brane quadratic divergences. We show by an explicit calculation in the orbifold S^1/Z_2 that such effects are absent at one-loop. Moreover we identify the symmetry that protects such brane mass terms to all orders in perturbation theory and thus guarantees the absence of a corresponding mass counterterm.

1 Introduction

The mechanism of electroweak symmetry breaking (EWSB) is one of the fundamental problems in particle physics. In particular, why this mechanism occurs at all or why the Higgs mass is much smaller than the *cutoff* of the low-energy effective theory: in fact the latter problem is dubbed as *hierarchy problem*.

In the Standard Model the sensitivity of the Higgs mass on the cutoff is quadratic, which translates into an accute hierarchy problem. In fact one could solve the hierarchy problem by an (unnatural) fine-tuning of the parameters of the theory, which means that the hierarchy problem is mainly a *naturalness* problem. From that point of view the hierarchy problem is alleviated in effective theories from low-scale strings since there the cutoff is in the TeV range [1]. As we said, in these theories the hierarchy problem is alleviated but not solved if there is sensitivity of the electroweak observables to the cutoff. This is because the ultraviolet physics is unknown from the point of view of effective theories.

In four-dimensional theories two main solutions to the hierarchy problem have been proposed:

- A non-perturbative solution where the Higgs is a QCD-like fermion-condensate: technicolor.
- A perturbative solution where an extra symmetry cancels the quadratic divergences of the Standard Model: supersymmetry.

Supersymmetry is not the only symmetry that can protect the Higgs mass. In the presence of compact extra dimensions [2] of length $\sim 1/\text{TeV}$ a *gauge* symmetry can do the job leading to

[a] Talk given at the XXXVIIth Rencontres de Moriond, *Electroweak Interactions and Unified Theories*, Les Arcs, March 9-16, 2002

envisaging a perturbative non-supersymmetric solution [3–6] to the hierarchy problem[b]. In that case the Higgses should be identified with the (zero modes of) extra dimensional components of higher-dimensional gauge bosons. In particular for δ extra dimensions, $i = 1, \ldots, \delta$ there are δ bosons

$$H_i(x^\mu) = A_i^{(0)}(x^\mu) \tag{1}$$

transforming in the adjoint representation of the higher-dimensional gauge group. One of them should play the role of the Standard Model Higgs. In fact if H_i acquires a vacuum expectation value the Standard Model is spontaneously broken by the Hosotani mechanism [3].

2 Electroweak Hosotani breaking

The previously defined H_i field is massless at the tree-level. This obviously results from the higher-dimensional gauge invariance. The masslessness of the H_i field should hold at any order in perturbation theory if the extra dimensions were infinitely large. However for compact extra dimensions one expects that radiative corrections generate finite [7] squared mass terms as $1/R^2$, where R is the radius of the extra dimension. This term goes away in the limit $R \to \infty$ and one recovers the result of flat dimensions. Similarly, a quadratically divergent term is forbidden for the same reason. This phenomenon is well known in thermal field theory[c] where the temperature plays the role of the inverse radius.

The Hosotani breaking is finite for smooth manifolds, as toroidal compactifications. However toroidal compactifications are problematic and we need to compactify extra dimensions on *orbifolds* mainly for two reasons[d]:

- Higher dimensional theories are non-chiral. We need to project out the chiral partners of the Standard Model fermions: this is performed by the orbifold action.

- The Standard Model Higgs is not in the adjoint representation of the gauge group. We need on general grounds a gauge group $\mathcal{G}$ in the bulk that can be broken by the orbifold action to a subgroup $\mathcal{H}$ that coincides with, or contains, the Standard Model gauge group and where the Higgs fields H_i are $SU(2)$ doublets with the correct hypercharge assignments.

The latter comments lead to a sort of minimal scenario that has been worked out in Ref. [6] and that can be embedded in type I string constructions. The starting point is the higher-dimensional gauge group $\mathcal{G} = U(3)_c \times U(3)_w$. The $SU(3)_w$ contained in $U(3)_w$ is broken down by the orbifold action into $SU(2) \times U(1)$ while the $SU(3)_c$ in $U(3)_c$ commutes with the orbifold action. The Standard Model Higgses are identified by the decomposition of the adjoint representation of $SU(3)_w$ into $SU(2) \times U(1)$ as

$$\mathbf{8} = \mathbf{3}_0 + \mathbf{1}_0 + \mathbf{2}_3 + \bar{\mathbf{2}}_{-3} \tag{2}$$

In this way the Standard Model gauge bosons are defined as the zero-modes of $\mathbf{3}_0^\mu + \mathbf{1}_0^\mu$ while the Higgs bosons are identified as the zero-modes of $\mathbf{2}_3^i + \bar{\mathbf{2}}_{-3}^i$ after the orbifold breaking.

The theory on the brane contains the Standard Model gauge group and two extra anomalous $U(1)$'s. They are broken by a generalized Green-Schwarz mechanism that cancels the anomalies and give masses to the corresponding $U(1)$ gauge bosons. The anomaly-free $U(1)$ coincides with the Standard Model hypercharge and is given by a linear combination of the three original $U(1)$'s.

[b] Of course this statement is made modulo the existence of a mechanism (involving the gravitational sector) that fixes the radii of the extra dimensions, as we will assume in this note.

[c] Here the time in the Euclidean four dimensional theory is compactified on a circle.

[d] There exist solutions to this problem involving smooth manifolds in the presence of non-trivial backgrounds [8].

Assuming unification of all gauge couplings, equal to g, at the string scale the hypercharge coupling is related to g as $g_Y^2 = 3g^2/11$ and the electroweak angle at the string scale is

$$\sin^2\theta_w = \frac{3}{14} \simeq 0.24 \tag{3}$$

This value is compatible with a multi-TeV string scale [9].

So far so good. We have seen that in a Hosotani breaking the higher-dimensional gauge invariance protects squared masses for the Higgs sector H_i from quadratic divergences in the bulk. However, as we have seen, chirality requires compactification on an orbifold. An orbifold has fixed points with four-dimensional boundaries where radiative effects can be localized. Unlike radiative corrections in the bulk, those localized on the branes are consistent with the symmetries of a four-dimensional theory and therefore we should worry about the possible appearance of quadratic divergences localized on the branes for the Higgs boson masses. The symmetries of the four-dimensional gauge theory valid on the brane do not protect Higgs boson masses from quadratic divergences, as happens for the Standard Model. In such a case, in spite of the protection in the bulk, we could re-create the hierarchy problem on the branes and the phenomenological relevance of the Hosotani breaking to solve the hierarchy problem would be jeopardized. A detailed calculation is then relevant. We present it in the next section where a simple Z_2 orbifold is analyzed in great detail.

3 Gauge theories on orbifolds

We have analyzed in detail brane effects on an orbifold $\mathcal{M}_4 \times S^1/Z_2$ that breaks an arbitrary gauge group $\mathcal{G}$ to its subgroup $\mathcal{H} \subset \mathcal{G}$ [10]. We split the generators of $\mathcal{G} = \{T^A\}$ into the generators of the unbroken subgroup $\mathcal{H} = \{T^a\}$ and the broken generators of the coset $\mathcal{K} = \mathcal{G}/\mathcal{H} = \{T^{\hat{a}}\}$. Our parity assignment is defined by

$$A_M^A(x^\mu, -x^5) = \alpha^M \Lambda^{AB} A_M^B(x^\mu, x^5) \quad \text{(no sum over M)} \tag{4}$$

$$c^A(x^\mu, -x^5) = \Lambda^{AB} c^B(x^\mu, x^5) \tag{5}$$

$$\Psi(x^\mu, -x^5) = \lambda_R \otimes (i\gamma^5)\Psi(x^\mu, x^5), \tag{6}$$

where Λ and $\lambda_R \otimes (i\gamma^5)$ represent the Z_2 action on the gauge bosons and FP-ghosts, and the fermions respectively (λ_R acts on the representation indices), $\gamma^5 = diag(-i, i)$ and $\alpha^\mu = +1$, $\alpha^5 = -1$. In addition, Λ is a symmetric matrix that squares to one: it is an orthogonal matrix. On the other hand λ_R is a hermitian matrix that squares to one: it is a unitary matrix.

Consistency of the 5D gauge symmetry with the orbifold action requires the condition [11]

$$f^{ABC} = \Lambda^{AA'}\Lambda^{BB'}\Lambda^{CC'} f^{A'B'C'}, \tag{7}$$

where summation over repeated indices is understood. The above constraint comes from the requirement that under the Z_2 action $F_{MN}^A \to \alpha^M \Lambda^{AB} F_{MN}^B$ (no sum over M), so that $F_{MN}^A F^{AMN}$ is invariant and it is straightforward to check that it is an automorphism of the Lie algebra of $\mathcal{G}$. With no loss of generality we can diagonalize $\Lambda^{AA'} = \eta^A \delta^{AA'}$ with $\eta^A = \pm 1$, consequently Eq. (7) takes the simpler form

$$f^{ABC} = \eta^A \eta^B \eta^C f^{ABC} \quad \text{(no sum)}. \tag{8}$$

For fermions, the requirement that the coupling $igA_M^A \overline{\Psi}_R \gamma^M T^A \Psi_R$ is Z_2 invariant leads to the condition

$$\lambda_R T_R^A \lambda_R = \eta^A T_R^A, \tag{9}$$

which can be simplified to

$$[\lambda_R, T_R^a] = 0 \qquad \{\lambda_R, T_R^{\hat{a}}\} = 0. \tag{10}$$

Some comments are now in order:

- The presence of $i\gamma^5$ in (6) makes it that Ψ_L and Ψ_R have opposite parities. In particular this means that
  - Zero modes are *chiral*. Anomalies have then to be canceled as in the Standard Model
  - Non-zero modes are *non-chiral* and then anomaly free.
- The gauge group on the brane is $\mathcal{H}$ and only *even* fields can couple to the brane. In particular for scalar fields only $\partial_5^{2n} A_5^{\hat{a}}$ and $\partial_5^{2n+1} A_5^a$, for $n = 0, 1 \ldots$, can have non-zero couplings to the brane. We will make use of this fact later on.

We have analyzed [10] bulk and brane renormalizations effects from the one-loop diagrams in Fig. 1. The wavy lines refer to 5D gauge bosons A_M^A, $M = \mu, 5$ and $A = a, \hat{a}$, the dotted lines

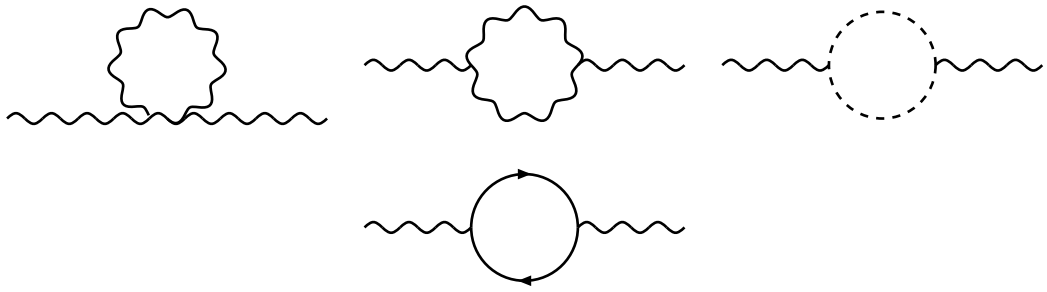

Figure 1: The one-loop diagrams contributing to mass and wave function renormalization

to the FP-ghosts c^A, $\bar{c}^A$ and the solid lines to the matter fermions Ψ in the representation $\mathbf{R}$ of $\mathcal{G}$.

From the diagrams in Fig. 1 with external momentum $p^\mu \neq 0$ there appear wave-function renormalization effects both in the bulk $\sim z_0 F_{MN}^A F_A^{MN}$, and on the branes

$$\sim \left[\delta(x^5) + \delta(x^5 - \pi R)\right] \left\{ z F_{\mu\nu}^a F_a^{\mu\nu} + \widetilde{z} F_{\mu 5}^{\hat{a}} F_{\hat{a}}^{\mu 5} \right\} \tag{11}$$

This phenomenon was first analyzed in Ref. [12].

We have studied mass renormalization effects, i.e. corresponding to zero external momentum $p^\mu = 0$, for gauge fields A_μ^A and scalar bosons A_5^A from the corresponding diagrams in Fig. 1. In this note we will concentrate on the case of external bosons $A_5^{\hat{a}}$ since they play the role of Higgs bosons on the brane and can spontaneously break the gauge symmetry $\mathcal{H}$ when they acquire a VEV.

3.1 Bulk effects

The most general terms that can appear in the bulk are given by the Lagrangian

$$\mathcal{L}_{bulk} = A_5^A \Pi_{AB}[-\partial_5^2] A_5^B \tag{12}$$

In particular the expansion of the $\Pi_{A\,B}[-\partial_5^2]$ operator around $p_5^2 = 0$ gives the squared mass term as $\Pi_{AB}[0] = -M_A^2 \delta_{A\,B}$, while the other terms in the expansion correspond to higher dimensional operators.

We obtain for the radiative mass in the bulk the expression

$$M_{bulk}^2 = \frac{3g^2}{32\pi^4 R^2}\zeta(3)\left[3C_2(\mathcal{G}) - 4\sum_R C_R\right] \tag{13}$$

where $C_2(\mathcal{G})$ is the Casimir of the group $\mathcal{G}$, C_R the Dynkin index of the representation $\mathbf{R}$ and the sum is understood to be performed over all different fermions in the theory. This result has been confirmed by the calculation of Ref. [13].

Here we can make two comments referring to the previous result:

- The radiative mass (13) if *finite*. In fact it is protected from quadratic divergences by the higher-dimensional gauge invariance.
- Fermions induce negative squared masses. They can induce vacuum expectation values for the $A_5^{\hat{a}}$ fields which in turn can trigger spontaneous breaking of the gauge theory $\mathcal{H}$ on the brane: the Hosotani breaking.

3.2 Brane effects

The general terms that can appear on the brane for the A_5^A fields in the absence of space-time derivatives are of the form,

$$\mathcal{L}_{brane} = \big(\delta(x^5) + \delta(x^5 - \pi R)\big)\, A_5^A \widetilde{\Pi}_{AB}[i\overleftarrow{\partial}_5, i\overrightarrow{\partial}_5] A_5^B \tag{14}$$

and the arrows on the ∂_5 indicate the field whose derivative is to be taken. Power expansion of $\Pi_{AB}[i\overleftarrow{\partial}_5, i\overrightarrow{\partial}_5]$ around $p_5 = 0$ provides, as in the case of bulk corrections, the different radiative corrections on the brane. In particular the lowest order corrections can be written as:

$$\mathcal{L}_{brane} = \big(\delta(x^5) + \delta(x^5 - \pi R)\big)\left\{\tilde{z}_1 (A_5^{\hat{a}})^2 + \tilde{z}_2 A_5^{\hat{a}} \partial_5^2 A_5^{\hat{a}} + \tilde{z}_3 (\partial_5 A_5^a)^2 + \cdots\right\} \tag{15}$$

A one loop calculation yields [10]

$$\widetilde{\Pi}_{AB}[\,p_5, p_5'] \equiv 0 \tag{16}$$

where the previous identity should be understood when the operator $\widetilde{\Pi}_{AB}[\,p_5, p_5']$ is bracketed as in Eq. (14). In particular this means that all the coefficients in Eq. (15) vanish.

At first sight this result is a bit puzzling since even if the fields $A_5^{\hat{a}}$, $\partial_5^2 A_5^{\hat{a}}$, $\partial_5 A_5^a$ are scalar fields in four dimensions, still the symmetries of the 5D theory seem to protect these scalar fields on the brane from quadratic divergences. In the next section we will identify the custodial invariance on the brane.

4 Restrictions on brane terms from higher dimensional gauge symmetries

In this section we would like to clarify the implications of the higher dimensional gauge symmetry $\mathcal{G}$ on possible brane localized interactions. In the bulk, the local symmetry $\mathcal{G}$ is realized on the gauge fields A_M^A as

$$\delta_{\mathcal{G}} A_M^A = \partial_M \xi^A + f^{ABC} \xi^B A_M^C \tag{17}$$

After orbifolding the gauge symmetry is still intact provided the parity assignments for the fields A_M^A are chosen to satisfy the automorphism condition (7) consistent with the orbifold structure, as well as a similar condition for the gauge parameters

$$\xi^A(x^\mu, -x^5) = \Lambda^{AB}\xi^B(x^\mu, x^5). \tag{18}$$

On the branes $\mathcal{G}$ is broken down to the subgroup $\mathcal{H}$. The nonzero fields are the gauge bosons of $\mathcal{H}$, $A_\mu^a(0)$, and the scalars $A_5^{\hat{a}}(0)$. Evaluating Eq. (17) at $x_5 = 0$ one gets for transformations generated by ξ^a

$$\delta_{\mathcal{H}} A_\mu^a = \partial_\mu \xi^a + f^{abc}\xi^b A_\mu^c, \tag{19}$$

$$\delta_{\mathcal{H}} A_5^{\hat{a}} = f^{\hat{a}b\hat{c}}\xi^b A_5^{\hat{c}}. \tag{20}$$

All fields and parameters are understood to be evaluated at $x_5 = 0$ and only depend on x^μ. The other terms present in Eq. (17) can be seen to vanish by parity by using that only the structure constants with zero or two hatted indices are nonzero, i.e. $f^{\hat{a}bc} = f^{\hat{a}\hat{b}\hat{c}} = 0$. Eq. (19) just means that $A_\mu^a(0)$ transforms as a gauge boson for the brane gauge symmetry $\mathcal{H}$, while Eq. (20) shows that the scalars transform in a representation given by

$$\left(T^b\right)_{\hat{a}\hat{c}} \equiv i f^{\hat{a}b\hat{c}}. \tag{21}$$

It is easy to show that the T^b indeed form a (not necessarily irreducible) representation of $\mathcal{H}$. All brane interactions must respect the symmetry $\mathcal{H}$ acting as in Eqs. (19) and (20).

However, there is a further remnant of $\mathcal{G}$ on the branes [e]: Doing the same reduction of Eq. (17) but this time for the odd parameters $\xi^{\hat{a}}$ one gets

$$\delta_{\mathcal{K}} A_\mu^a = 0, \tag{22}$$

$$\delta_{\mathcal{K}} A_5^{\hat{a}} = \partial_5 \xi^{\hat{a}}. \tag{23}$$

Eq. (23) is a local (i.e. x^μ-dependent) $\mathbb{R}^{d_{\mathcal{K}}}$ shift symmetry (and it is worthwhile to notice that it takes the same form for finite ξ as well). Its most important implication is that it forbids mass terms for the scalars on the branes as they appear for instance in Eq. (15) since

$$\delta_{\mathcal{K}}\left(A_5^{\hat{a}} M_{\hat{a}\hat{c}} A_5^{\hat{c}}\delta(x_5)\right) = 2A_5^{\hat{a}} M_{\hat{a}\hat{c}}\partial_5\xi^{\hat{c}}\delta(x_5) \neq 0. \tag{24}$$

In principle, one can derive infinitely many [f] constraints from the original gauge symmetry by taking powers of ∂_5 of Eq. (17) and evaluating at $x_5 = 0$. This yields for example

$$\delta_{\mathcal{K}}\left(\partial_5 A_\mu^{\hat{a}}\right) = \left(\mathcal{D}_\mu\right)^{\hat{a}\hat{c}}\left(\partial_5\xi^{\hat{c}}\right), \tag{25}$$

where $\mathcal{D}_\mu = \partial_\mu + iA_\mu^b T^b$ is the $\mathcal{H}$-covariant derivative in the representation Eq. (21). From this one sees that

$$\left(\mathcal{D}_\mu\right)^{\hat{a}\hat{c}} A_5^{\hat{c}} - \partial_5 A_\mu^{\hat{a}} \tag{26}$$

has vanishing variation $\delta_{\mathcal{K}}$ which is not surprising since Eq. (26) is just the field strength

$$F_{\mu 5}^{\hat{a}}(x_5 = 0)$$

which appears from the wave function renormalization on the brane, Eq. (11). Along these lines one could obtain all brane symmetries induced by the original gauge symmetry Eq. (17) and so restrict the possible localized terms.

[e] We thank R. Sundrum for bringing this to our minds.

[f] It is rather counterintuitive that the single gauge transformation Eq. (17) implies infinitely many transformations of the fields on the branes. This is due to the dependence $\xi = \xi(x_5)$ which translates to infinitely many independent transformation parameters $\partial_5^n \xi^{\hat{a}}\big|_{x_5=0}$.

5 Conclusions

In this note we have explored a non-supersymmetric alternative to the solution of the hierarchy problem (here understood as the appearance of quadratic divergences for the Higgs boson mass). This alternative is realized if electroweak symmetry breaking is triggered by the vacuum expectation value of the extra dimensional component of a higher dimensional gauge boson: the Hosotani mechanism.

A higher dimensional theory is non-chiral and to achieve four-dimensional chirality it requires an orbifold compactification. For this mechanism to hold the higher dimensional gauge group $\mathcal{G}$ must be broken by orbifolding to the Standard Model gauge group in such a way that the corresponding Higgs bosons have the Standard Model quantum numbers and interactions.

The Higgs mass is zero at tree-level. It is protected in the bulk from quadratic divergences by the higher-dimensional gauge invariance. It can however get by radiative corrections a tachyonic mass $\sim 1/R$ that can break spontaneously the Standard Model by the Hosotani mechanism.

For the Higgs mass we have found no one-loop quadratic divergences localized on the four-dimensional branes in spite of the fact that scalar Higgs boson masses are not protected by any four-dimensional symmetry on the brane. There is however a remnant of the higher-dimensional gauge invariance that forbids such mass terms. This custodial symmetry should be effective at any order in perturbation theory and so we do not expect any mass counterterms at higher loops. Of course this does not mean that there are not higher-loop divergences since they will be implemented by wave-function renormalization on the brane. This divergence should however be absorbed into the running of the gauge coupling.

Let us finally mention that this mechanism is suitable to low-scale string models and points towards the unification of electroweak theory into an $SU(3)$ group as the simplest possibility with $\sin^2\theta_W \simeq 0.25$.

Acknowledgments
